

Case Ritchie Bros: Quick win

DIAGNOSIS

Users wait around **15 seconds** to access auction items after clicking “**View items**,” creating unnecessary friction in a high-intent moment.

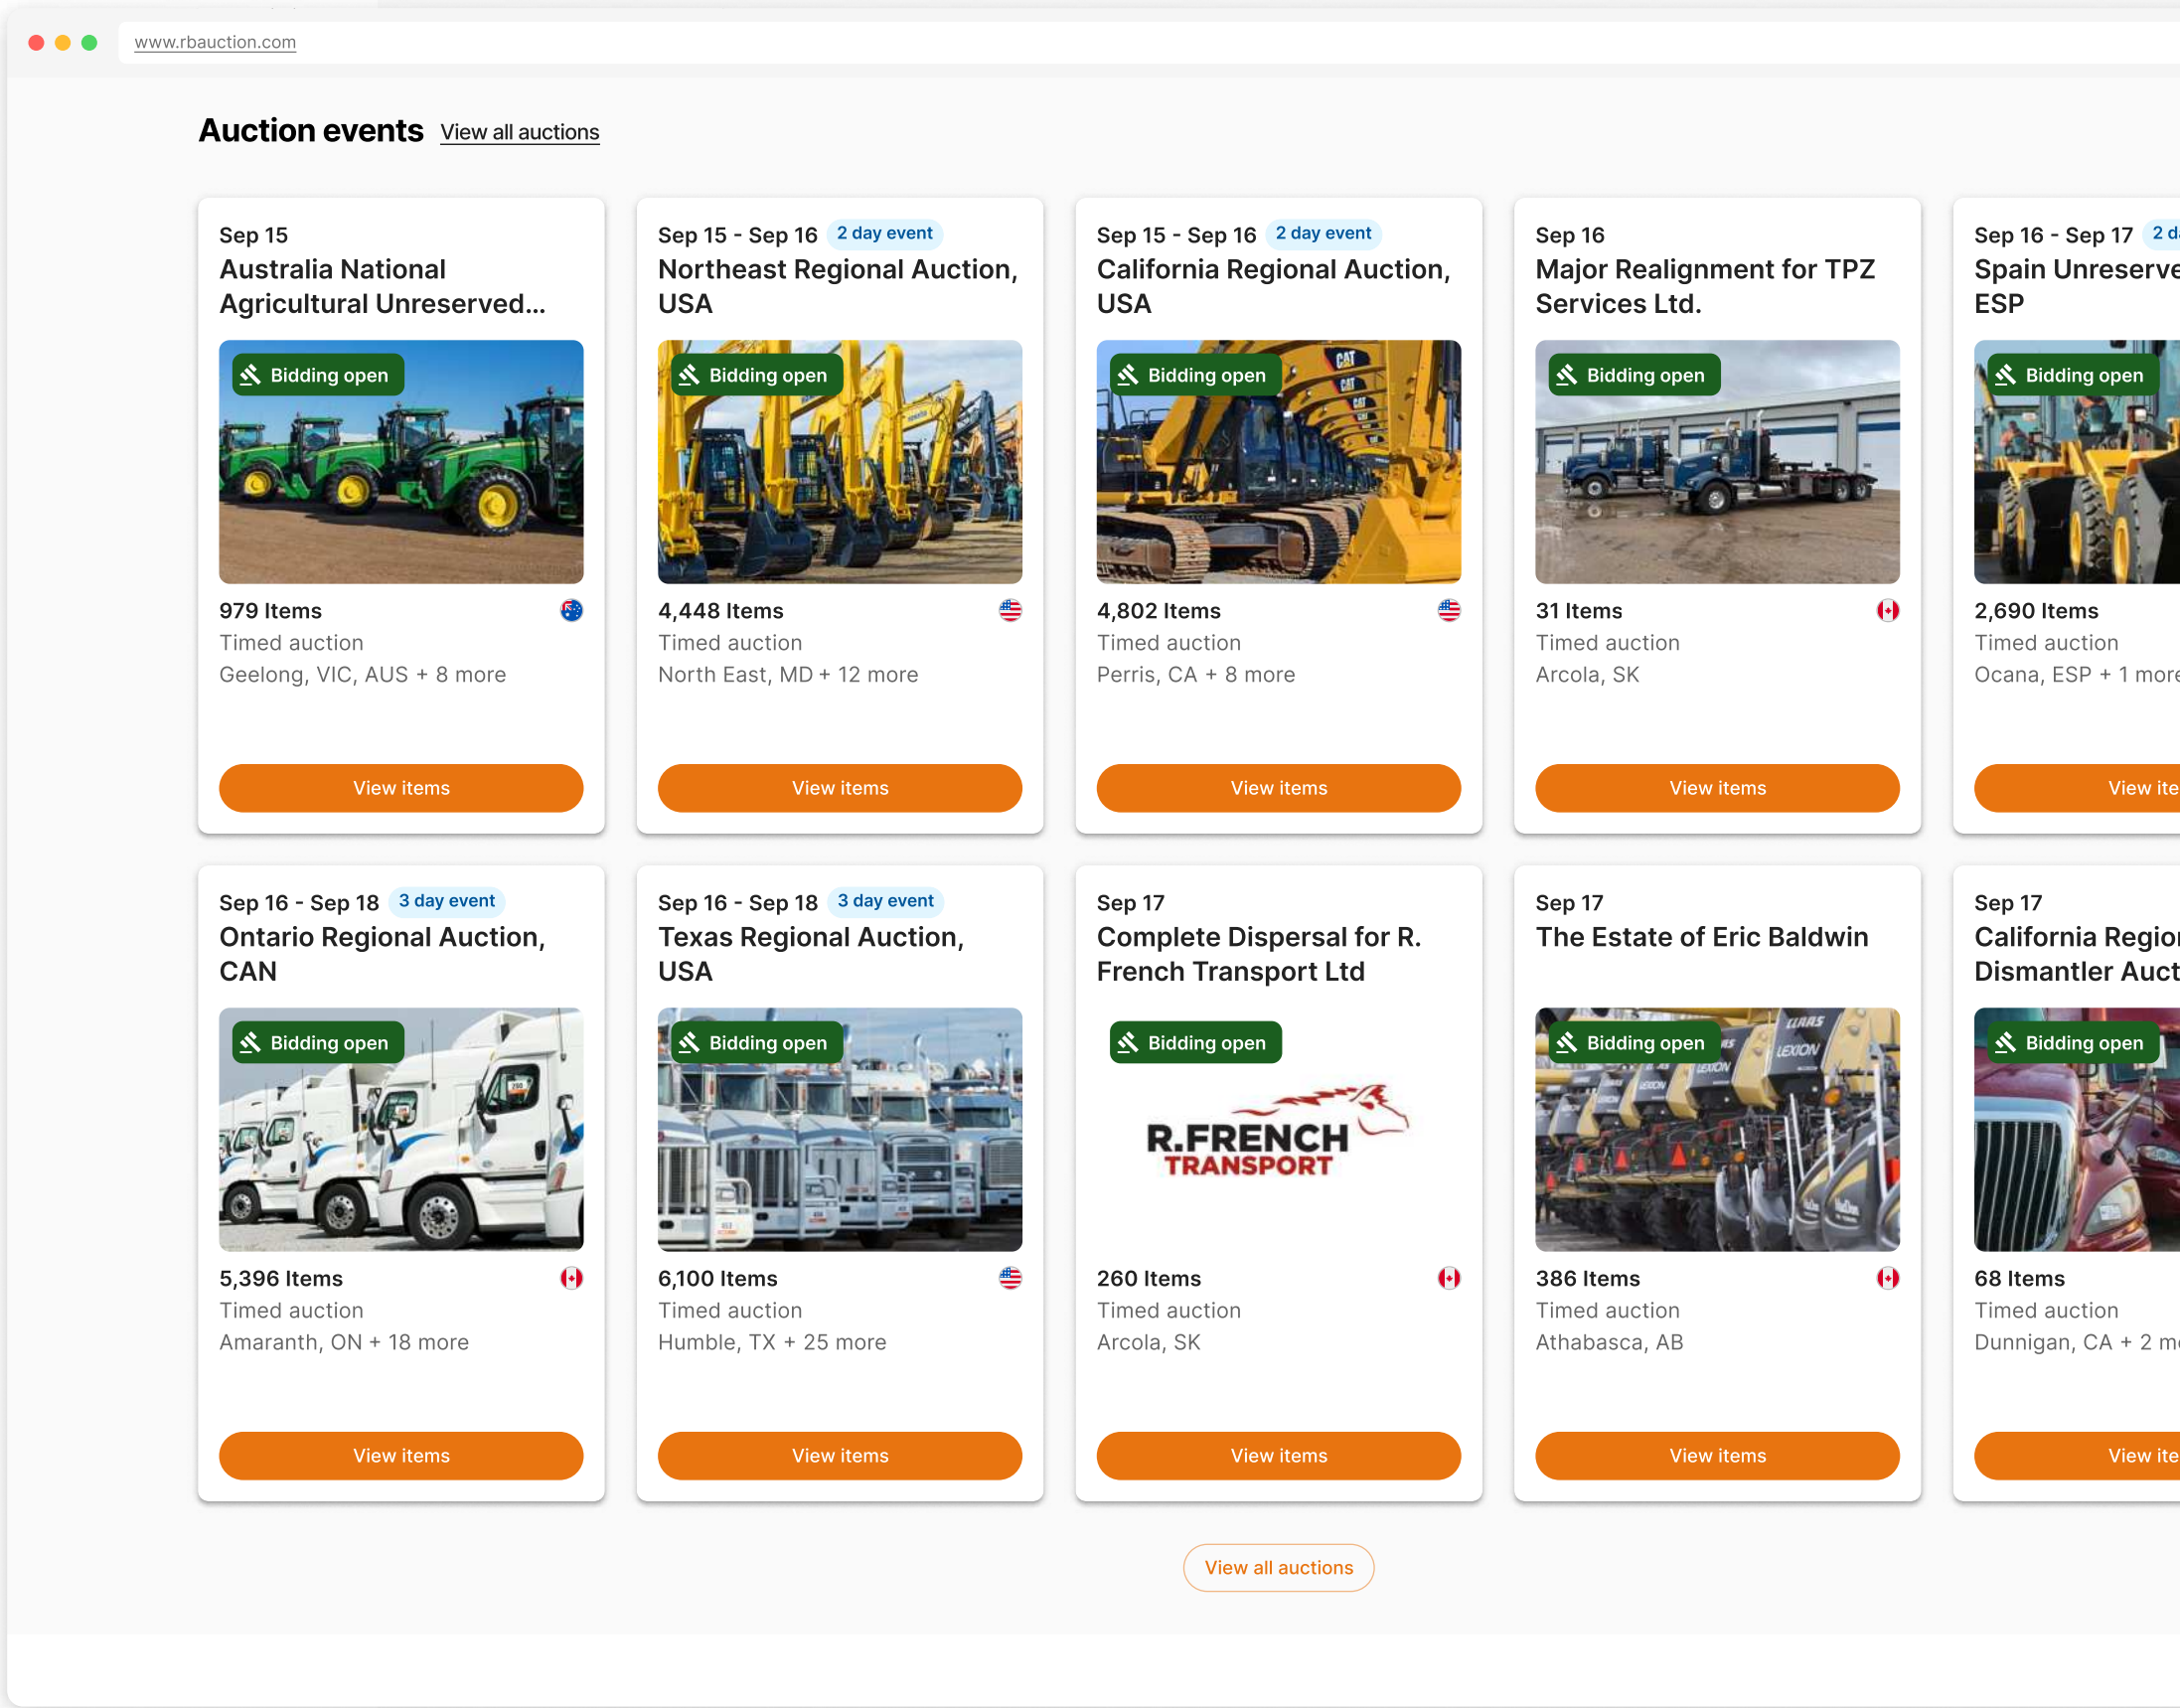

USER POINT OF VIEW

Users perception

When a website or application loads quickly, users are likely to perceive it as responsive and easy to use.

On the other hand, if a website or application takes too long to load, users may perceive it as slow and unresponsive. This can in turn negatively impact their overall experience

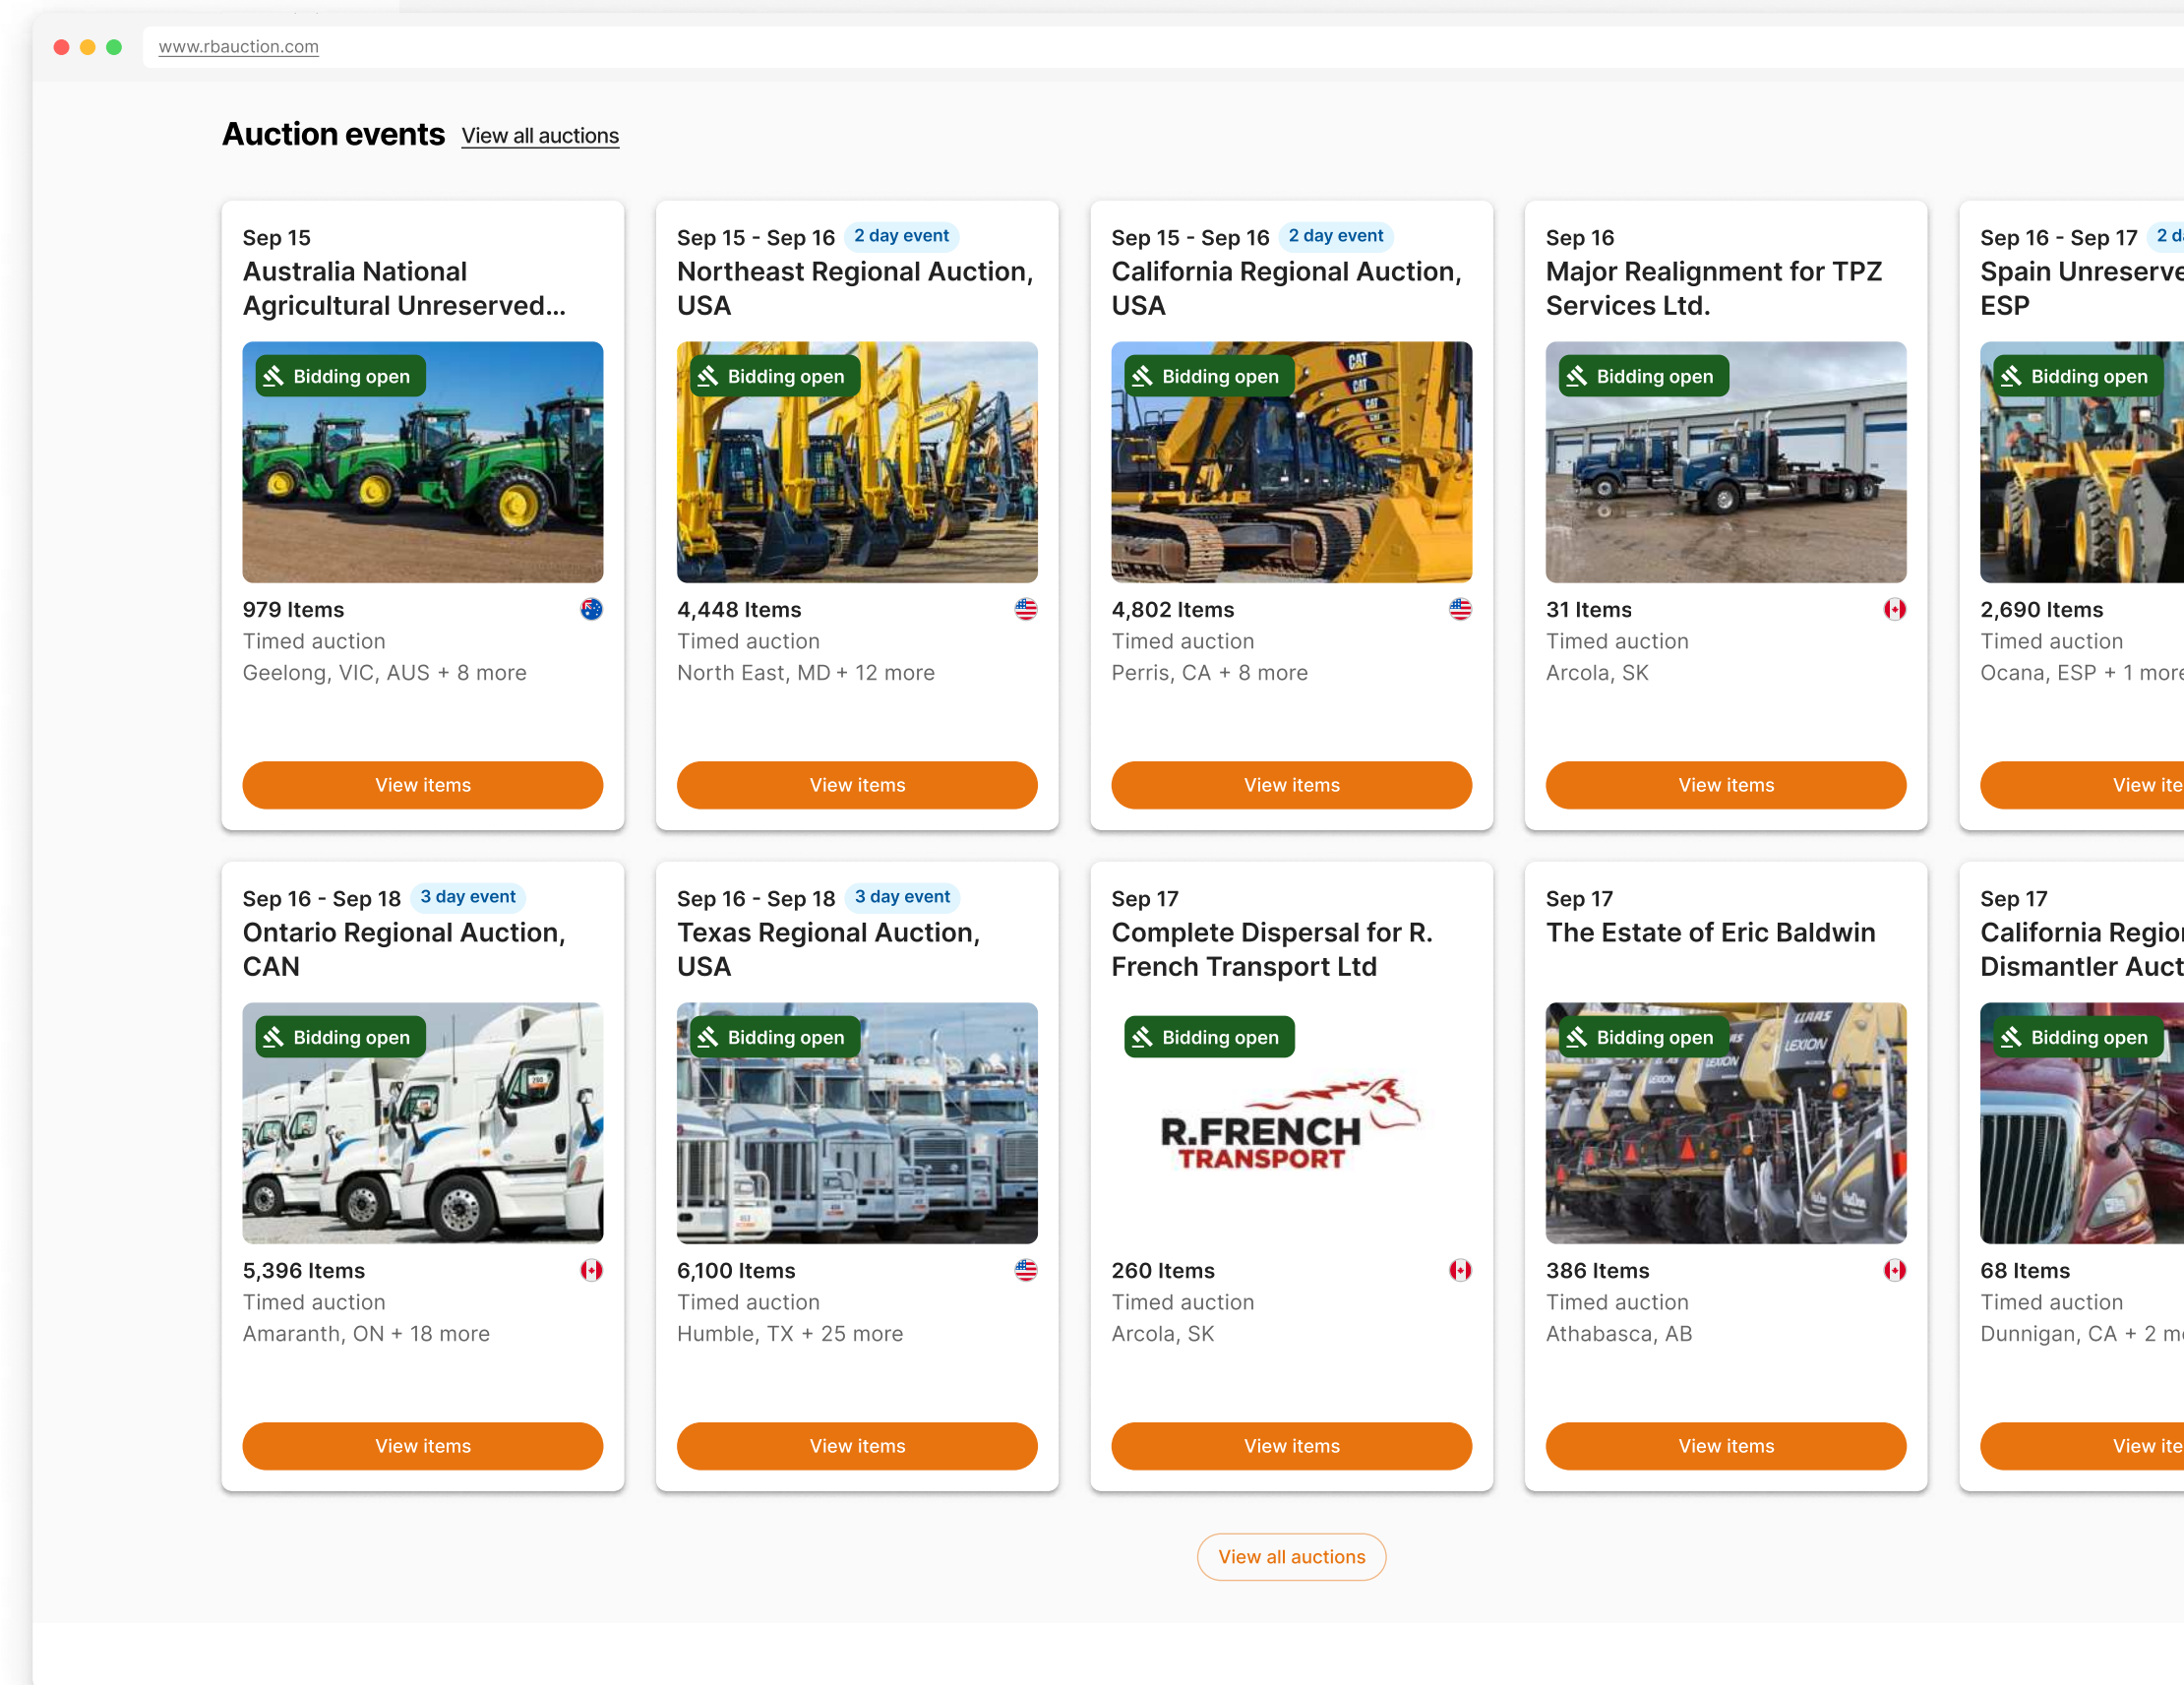

QUESTION

How fast do the website have to be?

It's depending on exactly what type of users experience we are aiming for.

My first suggestion is to check the time of responsive from competitors like:

Auctiontime, bidadoo and purplewave.

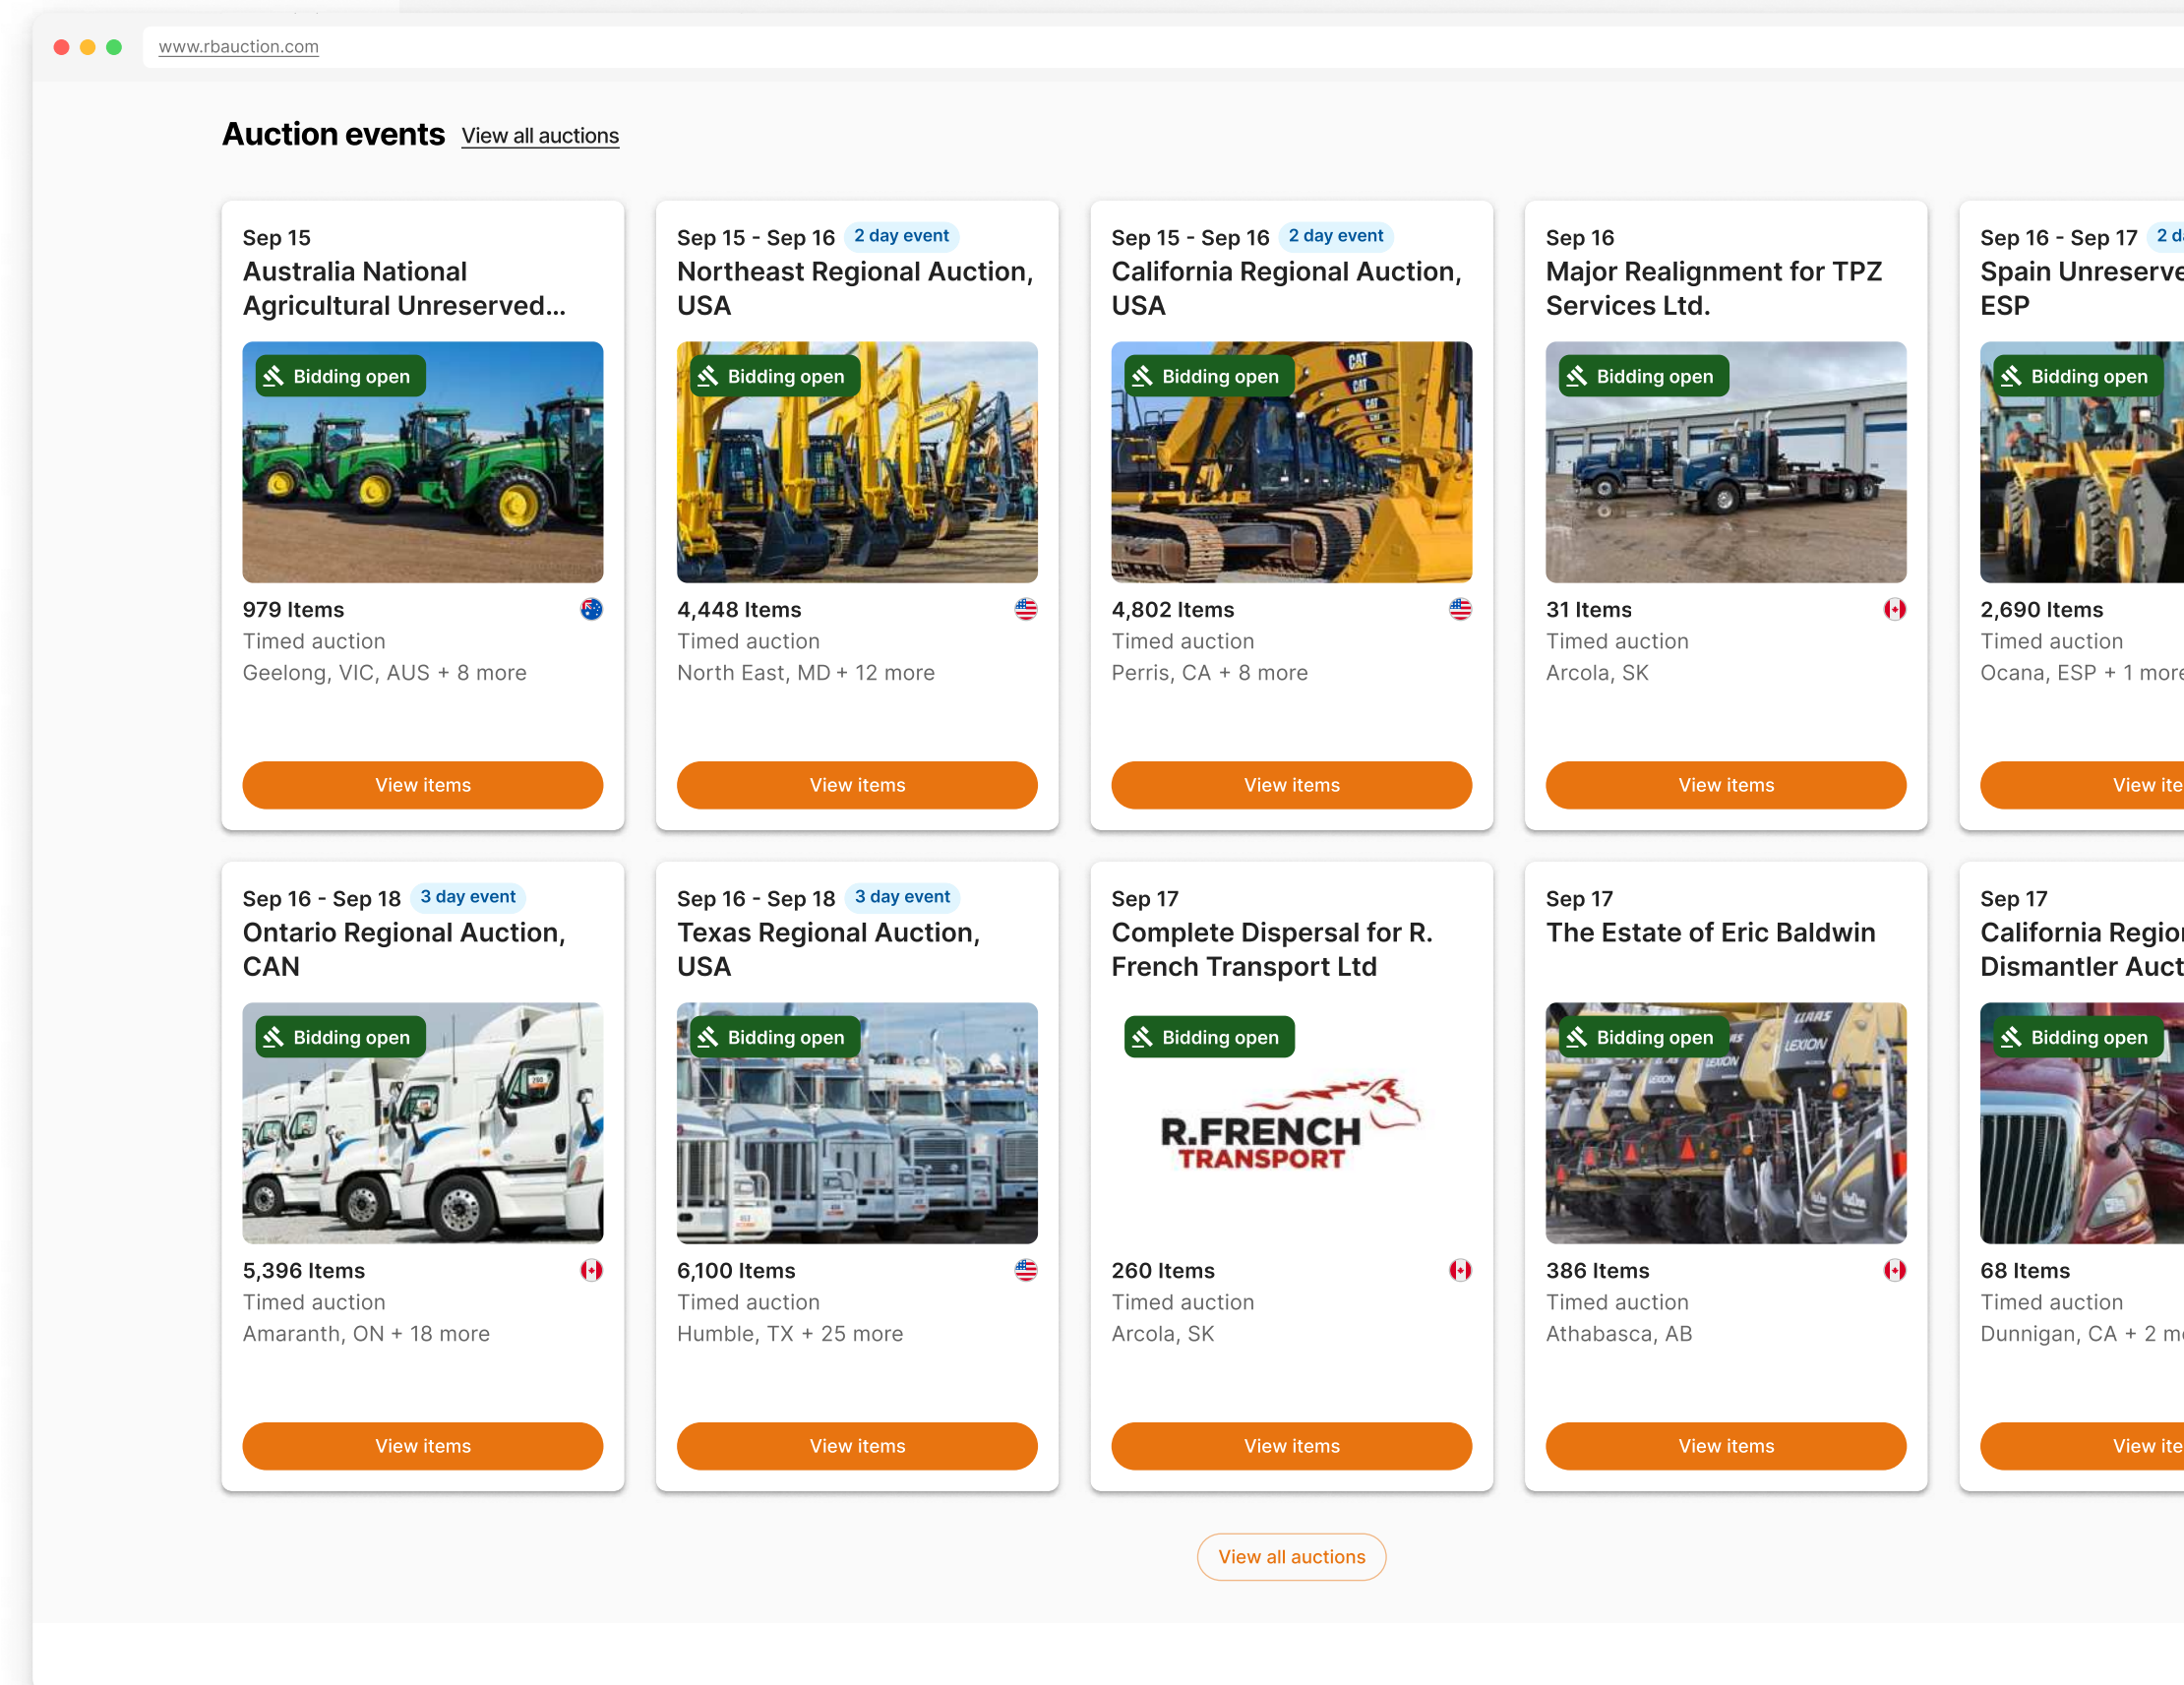

GOAL

10 seconds is good enough

For users to freely use the website and not worry about being slowed down by the computer

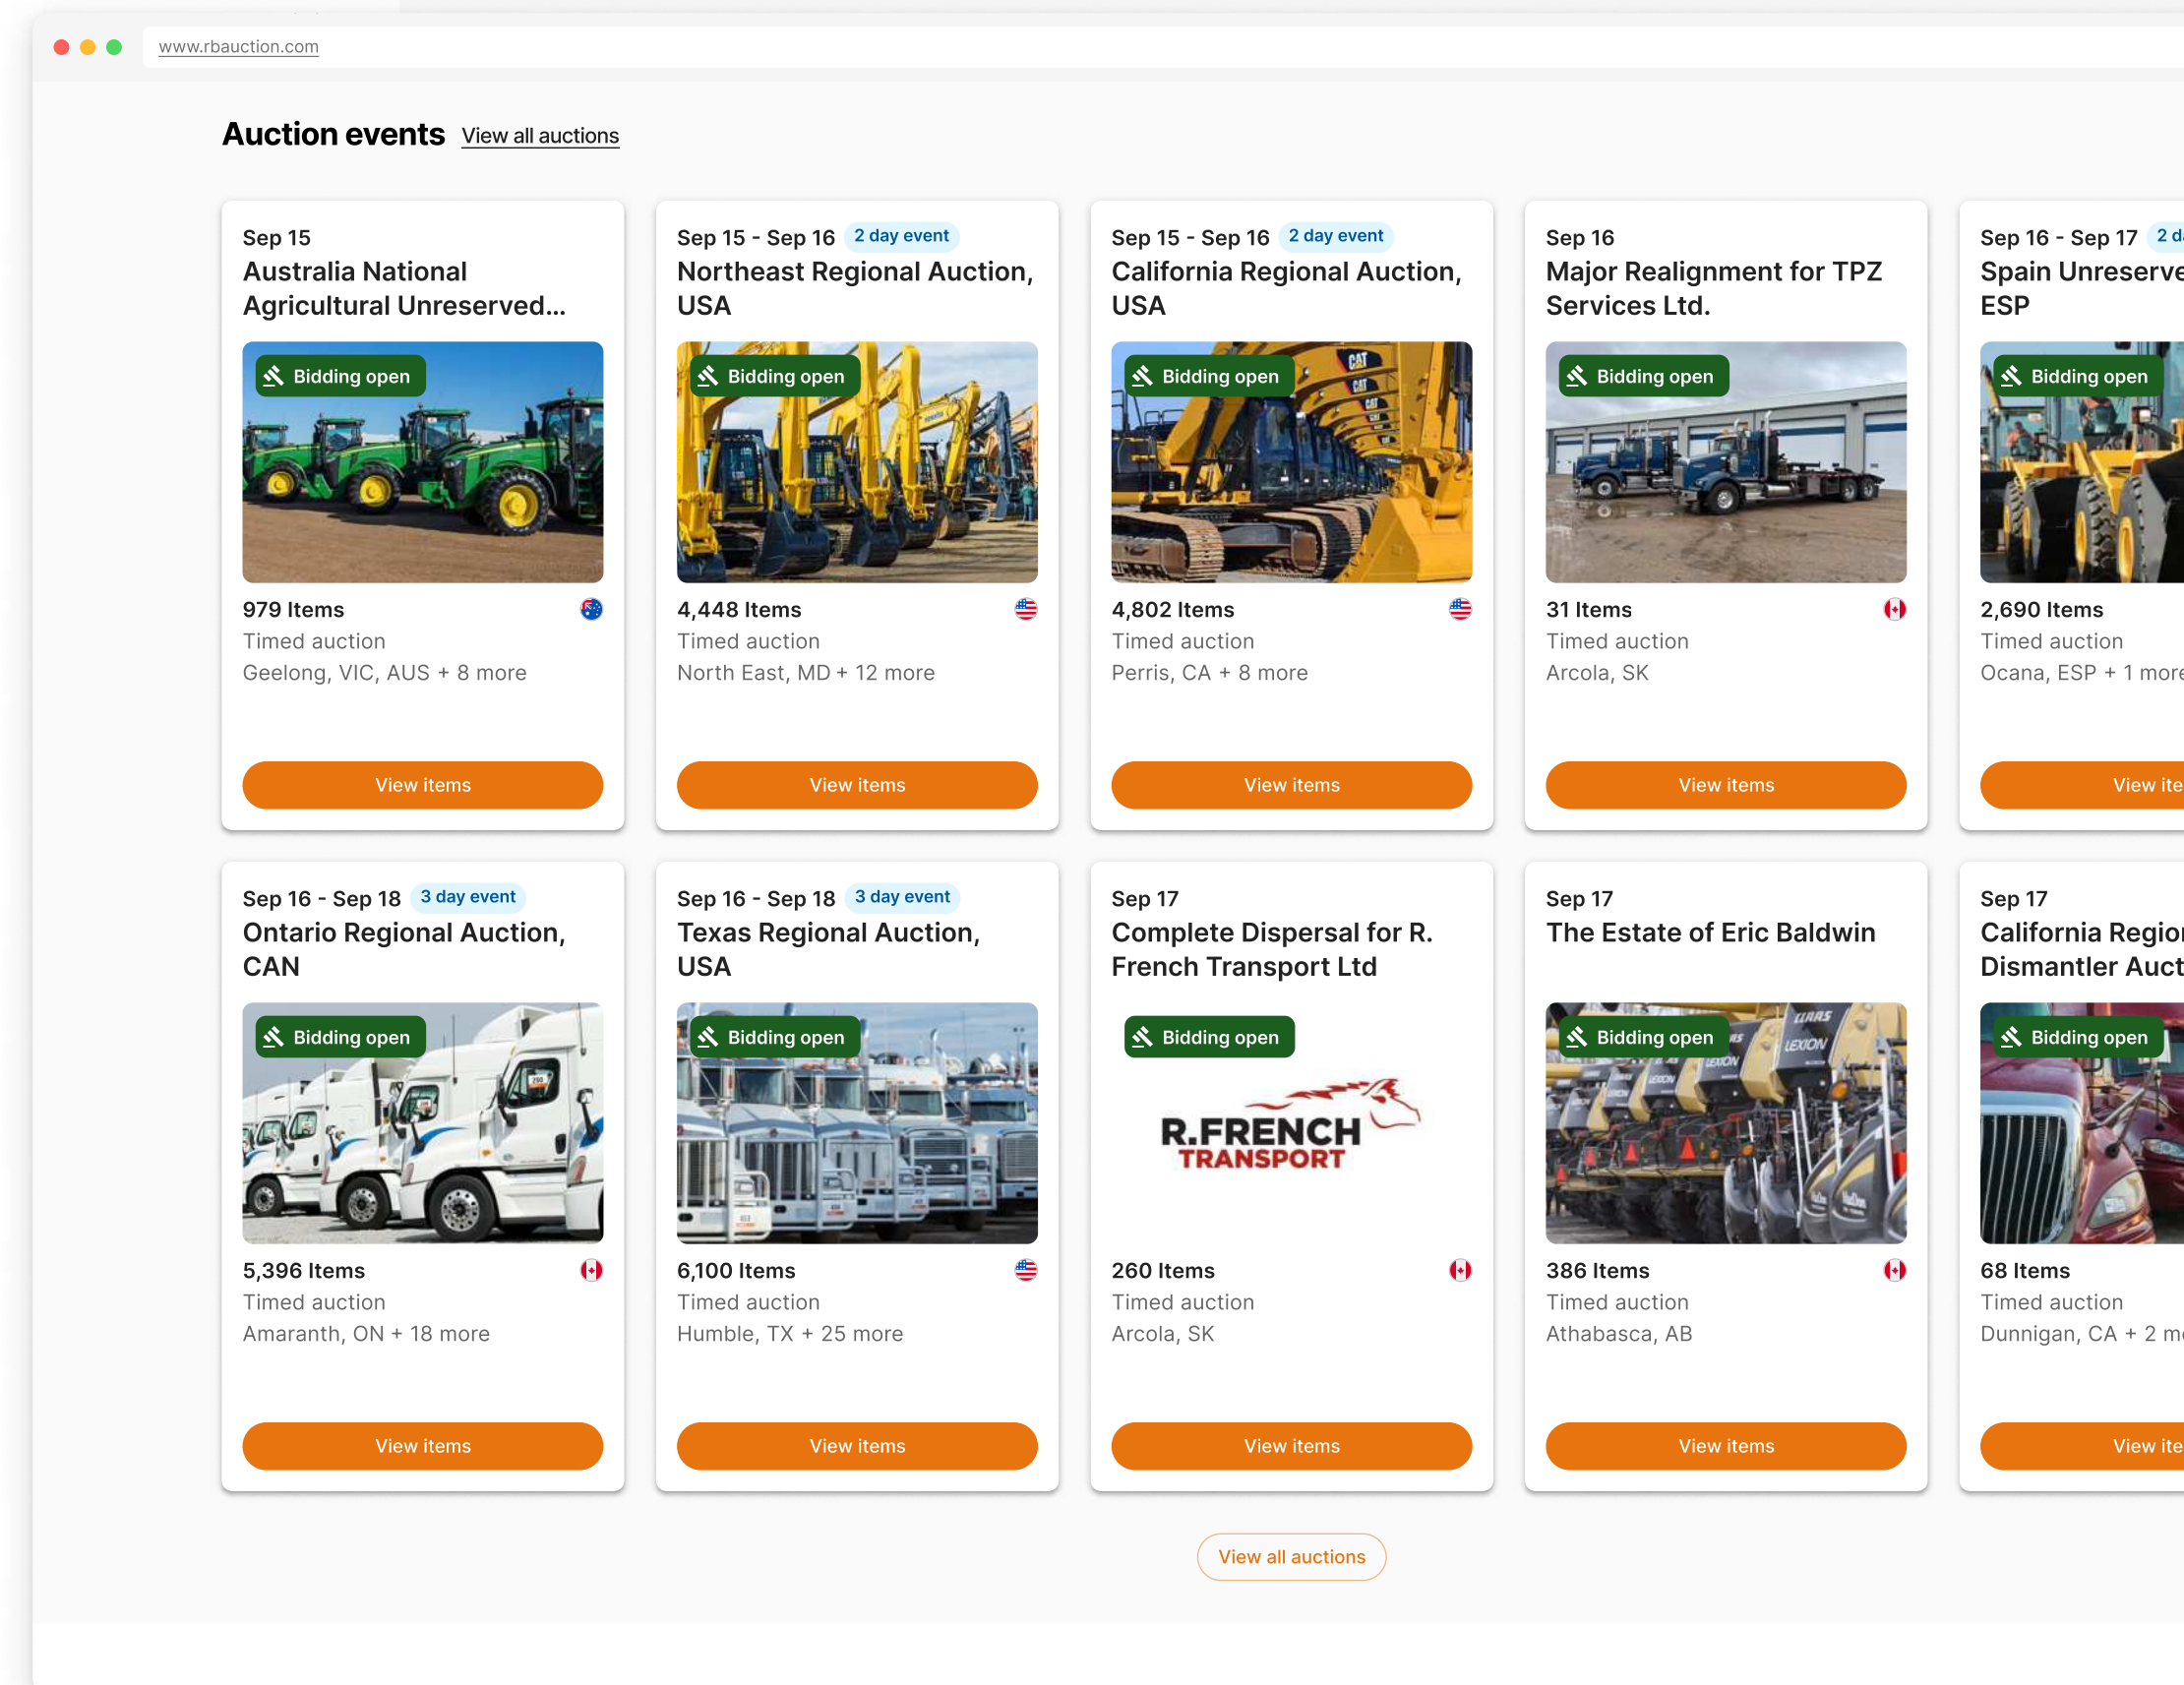

USABILITY ISSUE

Needs clearer user feedback

When users click “View items,” the interface should provide immediate feedback, such as a loading spinner, since the next page can sometimes take up to 15 seconds to load.

Could we be more
than a flyby?
